# Motivation: Vote-Buying Literature Forgets About Vote-Sellers

Clientelism: "the distribution of rewards to individuals or small groups during elections in contingent exchange for vote choices" (Nichter, 2014).

- The clientelism literature has focused primarily on vote-buying (parties buying) votes in exchange of electoral support).
- Unfortunately, we are rather ignorants about vote-sellers.
- \* Supply and demand story: Do parties target likely voters? Why? At what price? Under what conditions do sellers sell their votes?

Motivation

# Plan for Today

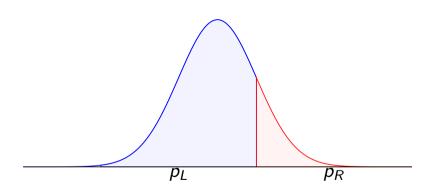

- 1. Formalize our theory and mechanisms.
- 2. Explain experimental design.
- 3. Feedback!

- *n* voters, each citizen *i* has an ideal point  $x_i$  which is an *iid* draw from an uniform distribution  $\Gamma = \{1, 2, ..., 100\}$ .
- When policy  $\gamma$  is implemented, payoffs of citizen i are given by  $u(D, x_i, \gamma) = D |x_i \gamma|$ .
- Two candidates ("left-wing" and "right-wing"). Each represents a policy which is an *iid* draw from an uniform distribution over  $\gamma_L \in \{1, ..., 50\}$  ( $\gamma_R \in \{51, ..., 100\}$ ).
- There are n<sub>L</sub> voters.

The Model

• Both parties negotiate with only one of these *n* voters who are randomly selected from the total population.

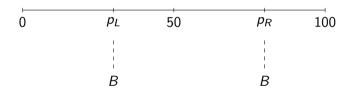

- Each candidate has a budget (B) that they can use to buy votes.
- Profits of party i are given by,

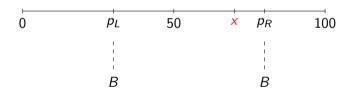

The Model

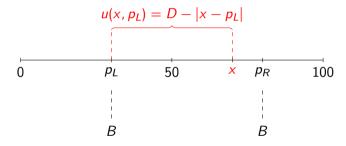

$$\pi_i(W, e_i, s_i) = W \cdot e_i + (1 - s_i \cdot a_j) \cdot B$$

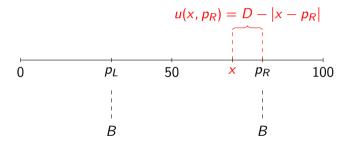

where W (W > B) is a constant that represents how much each party values winning the election,  $e_i = 1$  if party i wins the election, 0 otherwise,  $s_i$  is the fraction of B that the party offers to voter j who can accept the offer  $(a_i = 1)$  or not  $(a_i = 0)$ .

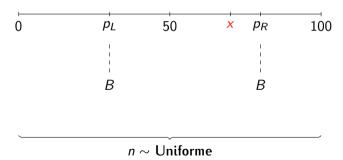

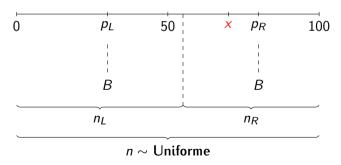

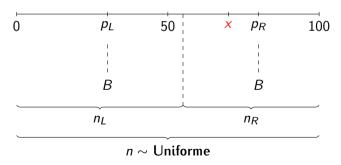

# Timing

• At the beginning of the game n voters and two political parties are randomly located on their respective ideal points: voters along  $\Gamma$ , and payoff relevant information is revealed.

### Vote-buying Case

The Model

- Each party simultaneously decides if making an offer to the voter.
- The voter decides if to take the offer (or which one, if there are two offers).
- Voter casts a ballot; if the voter accepts a party's offer, he should vote for that party.

### Vote-selling Case

- Voter may privately proposes a certain amount to each party in exchange for his vote.
- Parties decide if to pay or not the offer.
- Voter decides which one to accept, if any.
- Voter casts a ballot; if the voter accepts a party's offer, he should vote for that party.

# Equilibrium in Vote-Buying Case

• Parties only have incentives to negotiate with a voter *i* if he is the pivotal voter, this means:

$$|n_L - n_R| \le 1 \qquad \qquad i \in \max\{n_L, n_R\}$$

- Notation:  $i^* \in \{L, R\}$  the preferred party of the voter, and  $-i^*$  the other party.
- If the voter is pivotal, the less preferred party  $(-i^*)$  has incentives to offer him a certain amount  $m_{-i^*}$  such that:

$$m_{-i^*} \ge u(D, x_i, \gamma_{i^*}) - u(D, x_i, \gamma_{-i^*})$$

$$= (D - |x_{i^*} - \gamma_{i^*}|) - (D - |x_{i^*} - \gamma_{-i^*}|)$$

$$= |x_{i^*} - \gamma_{-i^*}| - |x_{i^*} - \gamma_{i^*}|.$$

# Equilibrium in Vote-Buying Case

- Parties want to win the election at a minimum cost, in equilibrium  $m_{i*}^* = 0$  and  $m^*_{i*} = |x_{i*} - y_{-i*}| - |x_{i*} - y_{i*}|.$
- The pivotal voter is indifferent between both political parties.
- Two Nash Equilibria.

- $\{(m_{i*}^*, m_{-i*}^*), \text{Accept offer } -i^*\}$
- { $(m_{i*}^*, m_{-i*}^*)$ , Reject offer  $-i^*$ }

# Equilibrium in Vote-Selling Case

- The voter has incentives to set the highest price each party can pay (this is given by B).
- The voter may swing towards party  $-i^*$  only if budget is large enough to compensate for looses if voting for his less prefer policy  $(B > |x_{i^*} y_{-i^*}| |x_{i^*} y_{i^*}|)$ .
- Note that if both parties accept to pay B to the voter, he will accept the offer of  $i^*$ .

## Equilibrium in Vote-Selling Case

• Then the parties,

The Model

• Nash Equilibria:  $\{(B, B), (Accept, Accept), Accept offer i^*\}$ 

#### Parts:

Experimental Design

- 1. **Vote-buying**: **parties** are first players (get out and buy votes, if needed).
- 2. **Vote-selling**: **voters** are first players (get out and sell votes, if needed).

#### Parts:

Experimental Design

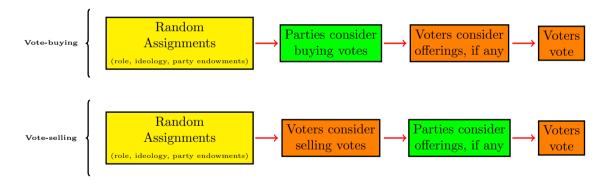

- 1. **Vote-buying: parties** are first players (get out and buy votes, if needed).
- 2. **Vote-selling**: **voters** are first players (get out and sell votes, if needed).

### For both parts, the following stages:

- 1. Random assignments: role  $(P_a, P_b, V_{\frac{1}{2}}, V_{\frac{1}{6}})$ , "ideology," "party endowments." Games are played among three subjects always: two parties, one voter.
- 2. buying/selling offers.
- 3. buying/selling choices.
- 4. Election: V: if her party wins, she wins \$], P: if he wins the election, he wins \$].

## Experimental Flow

••000000

### Caveats

- 1. Ideology: voters "lean" towards a party based on the amount of points received if party wins the election. Not really "ideology."
- 2. Party endowments: fixed. Parties face different relative vote-buying costs depending on party-voter distance. Proxy of "randomized" party endowment.
- 3. Relative importance of voter is randomized. Voters are told they represent  $\frac{1}{2}$  or  $\frac{1}{\epsilon}$  of voters (randomized & public knowledge).

# Comparative Statics: Ideology

- Downsian paradigm is unidimensional: left-right continuum (policy-oriented).
- We add some more complexity: a non-policy factor (vote-selling is *not* policy-oriented, Kitschelt 2007).
- Research question: What's the tipping point at which voters stop caring about ideology, and start selling their votes?
- Ideology given by party-voter spatial distance (randomized).

- Competitive authoritarian regimes survive not due to electoral fraud (Levitsky and Wau 2010).
- They survive because of the incumbent's capacity to mobilize a large mass of supporters, discouraging likely opposers (Magaloni 2008).
- Research questions:

**Experimental Design** 

- 1. At which point do parties feel encouraged and start buying votes?
- 2. At which point do parties feel discouraged and abandon the electoral race, not even buying votes?
- ★ Competitiveness given by  $\left[\frac{1}{3}, \frac{1}{5}\right]$  voter types (randomized).

## Comparative Statics: Endowments

- Literature won't give a definitive answer: Parties with more resources buy votes at higher prices (Bahamonde, 2018) or not (Szwarcberg, 2013).
- **Ultimately**, the question is: Does *expensive clientelism* exist?
- Research question: **Do wealthier parties buy more votes?**
- Remember caveat: not "really" randomized. Proxu.
- \* Relative party purchasing power varies according to party-voter spatial distance.

## Comparative Statics: Targeting

- Literature won't give a definitive answer:
  - Do parties target own supporters (since it's cheaper)? (Cox and McCubbins)
  - Do parties target unlikely voters (otherwise it's a waste)? (Stokes).
- Research question: Who do political parties target? Own? Unlikely?
- ★ Own/Unlikely are given at random.

# Comparative Statics: Sequence

• Research question: Does being the first one in making an offer matter? When? How?

### Feedback Wanted
